Hierarchical Diffusion-Based Offline RL

Offline Reinforcement Learning:

- policy learning without any environmental interaction
- extrapolation error caused by out-of-distribution states and actions
- mode-covering challenge from diverse hierarchical trajectories

Diffusion Models for Offline RL:

- building diffusion-based policies with strong generative capacity
- reframing decision-making as offline trajectory generation
- exponential increase in estimate variance and high computational cost

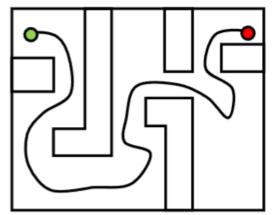

Hierarchical Diffusion for Offline RL:

- task decomposition into manageable subproblems
- introducing manually predefined skills into diffusion
- trajectory segmentation for subgoal-directed diffusion

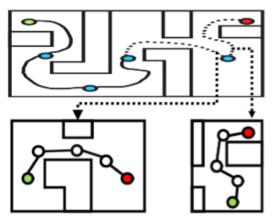

Hierarchical Diffusion-Based Offline RL

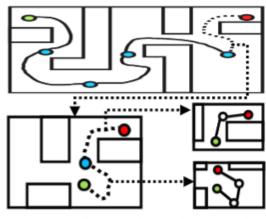

Illustrative Example For Hierarchical Trajectory Generation:

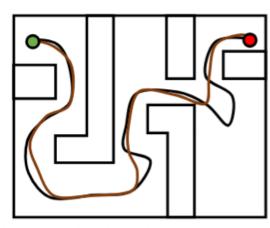

a) offline trajectory

b) 2-layer rigid diffusion

c) multi-scale hierarchy

d) regularized exploration

Summary:

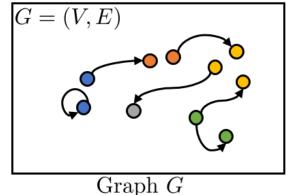

- single predefined temporal scale to segment offline trajectories
- fixed two-layer diffusion hierarchy composed of subgoal and action layers
- hindering adaptability to varying temporal patterns and task-specific complexities

Structural Information Principles

The structural entropy measures the uncertainty of a graph under a strategy of hierarchical partitioning, which is called an "encoding tree".

The encoding tree of G is defined as a rooted tree T with the following properties:

- 1) For each node $\alpha \in T$, there is a vertex subset in G corresponding with α , $T_{\alpha} \subseteq V$.
 - 2) For the root node λ , we set $T_{\lambda} = V$.
- 3) For each node $\alpha \in T$, its children nodes are marked as $\alpha^{\wedge}\langle i \rangle$ ordered from T left to right as i increases, and $\alpha^{\wedge}\langle i \rangle^{-} = \alpha$.
- 4) For each node $\alpha \in T$, we suppose that L is the number of its children nodes; then all vertex subsets $T_{\alpha^{\wedge}\langle i\rangle}$ are disjointed, and $T_{\alpha} = \bigcup_{i=1}^{L} T_{\alpha^{\wedge}\langle i\rangle}$.
 - 5) For each leaf node ν , T_{ν} is a singleton containing a single vertex in V.

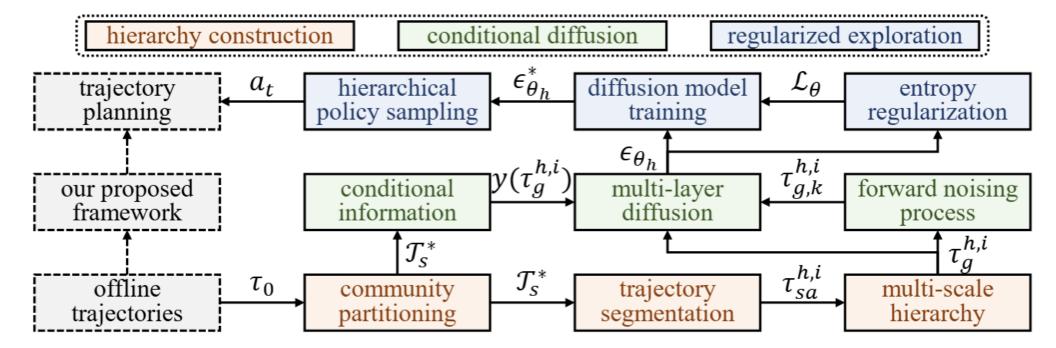

T $\alpha^{\wedge}\langle i\rangle$ ν Fraction Trac T

Encoding Tree T

Our Proposed Adversarial Attack Framework

Overall SIHD Framework:

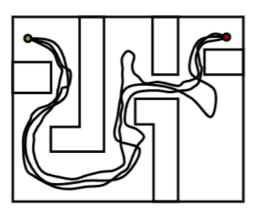

- structural information guided construction of adaptive multi-scale diffusion hierarchy
- conditional forward diffusion and reverse inference at multiple time scales
- encouraging regularized exploration for underrepresented offline states

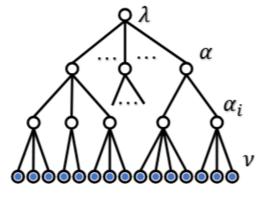

Our Proposed Hierarchical Diffusion Framework

Stage 1: Multi-Scale Diffusion Hierarchy

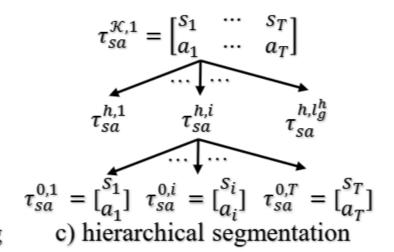

- leverage feature similarity to identify structural relationships among offline states
- derive a tree-structured partitioning of offline state communities
- construct the trajectory-adaptive multi-scale hierarchical diffusion instead of the rigid two-layer diffusion hierarchy operating at a single scale

a) offline trajectories

b) community partitioning

$$\tau_g^{\mathcal{K},1} = [g_i^{\mathcal{K}-1}]_{i=1}^{l_g^{\mathcal{K},1}}$$

$$\tau_g^{h,i} = [g_{\sum_{k=1}^{i-1} l_g^{h,k} + j}^{h,i}]_{j=1}^{l_g^{h,i}}$$

$$\tau_g^{1,i} = \tau_{sa}^{1,i}$$

d) multi-layer subgoals

Our Proposed Hierarchical Diffusion Framework

Stage 2: Conditional Diffusion Model

- generate a subgoal sequence conditioned on task rewards at the top of diffusion hierarchy
- generate subgoal sequences at intermediate levels of the hierarchy or state-action sequences at the base level, with each generation process conditioned on the parent subgoal
- compute the structural information gain as classifier-free guidance to enhance conditional hierarchical generation

Stage 3: Structural Entropy Regularizer

- introduce a structural entropy-based exploration regularizer
- encourage the hierarchical policy to explore underrepresented regions of the state space
- limit extrapolation errors resulting from deviations from the offline behavioral policy

Comparative Experiments on the D4RL Benchmark

Datasets: Gym-MuJoCo, Maze2D and AntMaze benchmark tasks

Background

 Baselines: model-free methods (CQL, IQL, and Decision Transformer), model-based methods (MoReL and Trajectory Transformer), diffusion-based methods (Diffuser, HDMI, HD)

Ablation Study on Primary SIHD Modules

- SIHD-DH: replacing the multi-scale hierarchy with a rigid two-layer single-scale diffuser
- SIHD-CG: removing the classifier-based guidance in conditional diffusion
- SIHD-ER: removing the structural entropy regularizer in policy learning
- highlighting the importance of each component and the critical role of the multi-scale diffusion hierarchy in SIHD
- becoming even more pronounced in long-horizon decision-making tasks

Conclusion and Future Works

- This work proposes SIHD, a novel hierarchical diffusion framework that leverages structural
 information embedded in historical trajectories to construct an adaptive multi-scale diffusion
 hierarchy and promote exploration of underrepresented states in offline datasets, thereby enabling
 effective policy learning.
- Extensive evaluations on the challenging D4RL benchmark demonstrate the superior decision-making performance and generalization capabilities of SIHD across diverse offline RL tasks.
- In future work, we aim to refine the hierarchical diffusion framework by further exploring how to more effectively represent and integrate subgoal constraints as conditional information.
- We also plan to extend the SIHD framework to other offline RL environments and broader diffusionbased generative modeling domains.

Structural Information-based Hierarchical Diffusion for Offline Reinforcement Learning
